A triangle that does not contain a right angle is called an **oblique triangle**.

An oblique triangle will have either three acute angles or one obtuse angle and two acute angles.

Acute Triangle
All angles acute

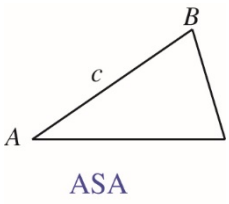

Obtuse Triangle
One angle obtuse

For an oblique triangle, given the length of a side and any other two parts of the triangle we can solve the triangle.

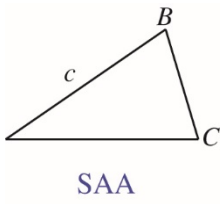

There are four distinct cases involving known angles (A) and known sides (S).

Solve a Triangle Using the Law of Sines (SAA or ASA)

Law of Sines If ΔABC is a triangle with sides of length a, b, and c opposite angles A, B, and C, respectively, then

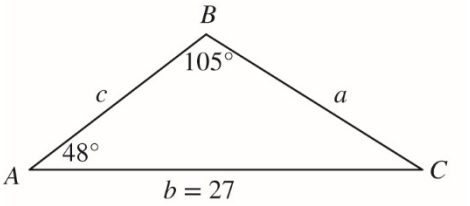

$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C} \quad \text{or} \quad \frac{\sin A}{a} = \frac{\sin B}{b} = \frac{\sin C}{c}.$$

The ratio of the length of a side of a triangle to the sine of the angle opposite that side is the same for all three side-angle combinations.

To apply the law of sines, we need to have one complete ratio and one other piece of information about the triangle (another side or another angle).

1. Solve the triangle. Round the lengths of sides and measures of the angles to 1 decimal place if necessary.

$\frac{a}{\sin 48} = \frac{27}{\sin 105}$

$a = \frac{27 \sin 48}{\sin 105}$

$a = 20.8$

$C = 180 - 105 - 48$

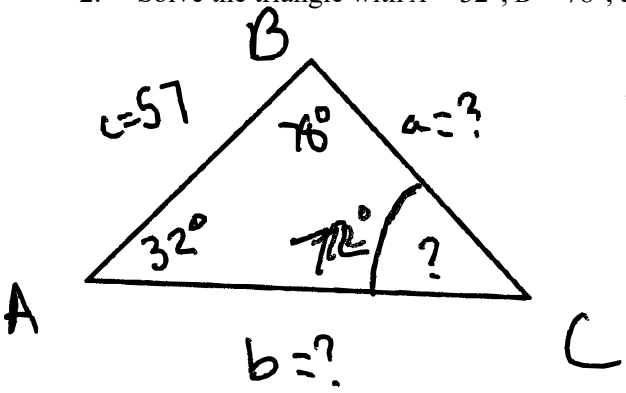

$C = 27°$

$\frac{c}{\sin 27} = \frac{27}{\sin 105}$

$c = \frac{27 \sin 27}{\sin 105}$

$c = 12.7$

2. Solve the triangle with $A = 32°$, $B = 78°$, and $c = 57$. Round the lengths of the sides to 1 decimal place.

$C = 180 - 78 - 32$

$C = 70°$

$\frac{b}{\sin 78} = \frac{57}{\sin 72}$

$b = \frac{57 \sin 78}{\sin 72}$

$b = 58.6$

$\frac{a}{\sin 32} = \frac{57}{\sin 72}$

$a = \frac{57 \sin 32}{\sin 72}$

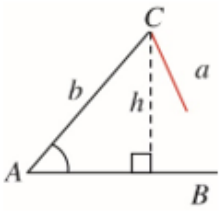

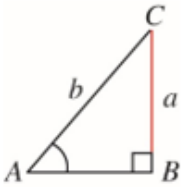

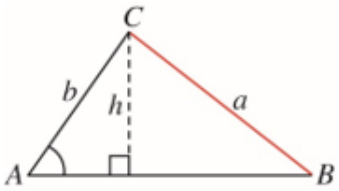

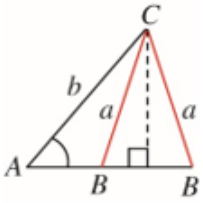

$a = 31.8$

Solve a Triangle Using the Law of Sines (SSA) Ambiguous Case

Suppose that the measure of angle A and the lengths of sides a and b of a triangle are given.

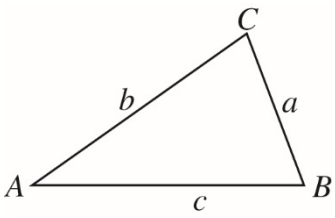

Depending on the length of side a (shown in red) relative to the length of the altitude h, we have four different scenarios.

No triangle	One right triangle	One oblique triangle	Two triangles: One acute and one obtuse triangle
			
$a < h$ Side a is too short to meet side c.	$a = h$ Side a exactly equals the altitude	$a > b$ One triangle possible	$h < a < b$ Side a intersects side c at an obtuse or acute angle.

Compute the Area of a Triangle given SAS

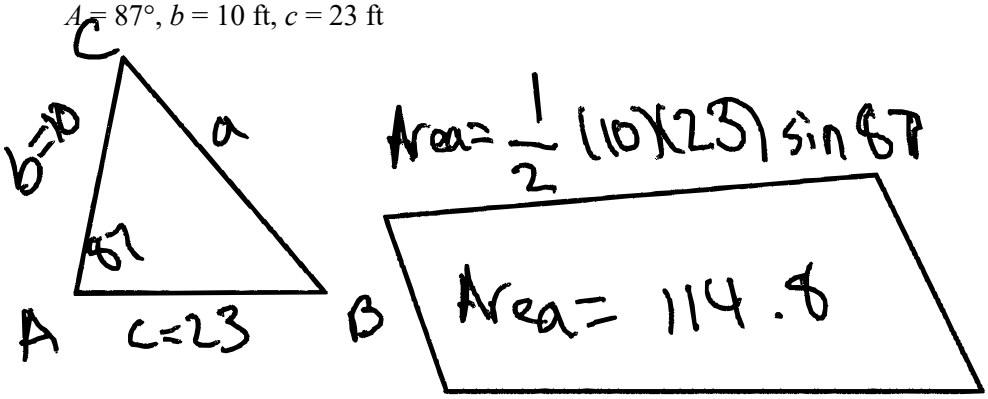

For a triangle ΔABC, the area of the triangle is given by

$$\text{Area} = \frac{1}{2}bc\sin A \quad \text{or} \quad \text{Area} = \frac{1}{2}ab\sin C \quad \text{or} \quad \text{Area} = \frac{1}{2}ac\sin B.$$

---

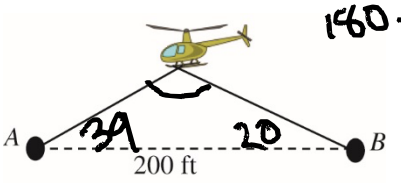

3. Find the area of a triangle with the given measurements. Round to one decimal place.
   $A = 87°$, $b = 10$ ft, $c = 23$ ft

Apply the Law of Sines

4. A helicopter is on a path directly overhead line AB when it is simultaneously observed from locations A and B separated by 200 ft. If the angle of elevation from A is 39° and the angle of elevation from B is 20°, what is the distance from each location to the helicopter? Round to the nearest foot.

$180-39-20 = 121$

$c = 200$

$\frac{200}{\sin 121} = \frac{a}{\sin 39}$

$a = \frac{200 \sin 39}{\sin 121}$

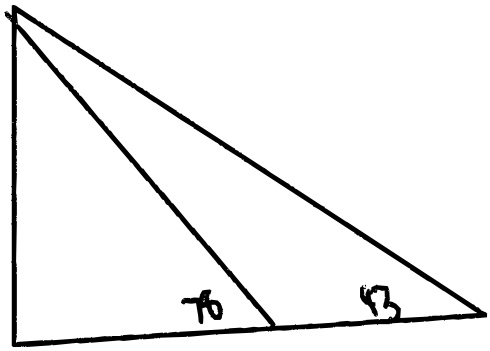

$a = 146.8$

$\frac{200}{\sin 121} = \frac{b}{\sin 20}$

$b = \frac{200 \sin 20}{\sin 121}$

$b = 79.8$

5. To estimate the height of a building, two measurements are taken. The first measurement shows an angle of elevation to the top of the building as 43°. The second measurement, taken 100 feet closer to the base, yields an angle of elevation of 78°. From these measurements, estimate the height of the building. Round to the nearest foot.

Dont need AFAIK
